

# Falling meteorite

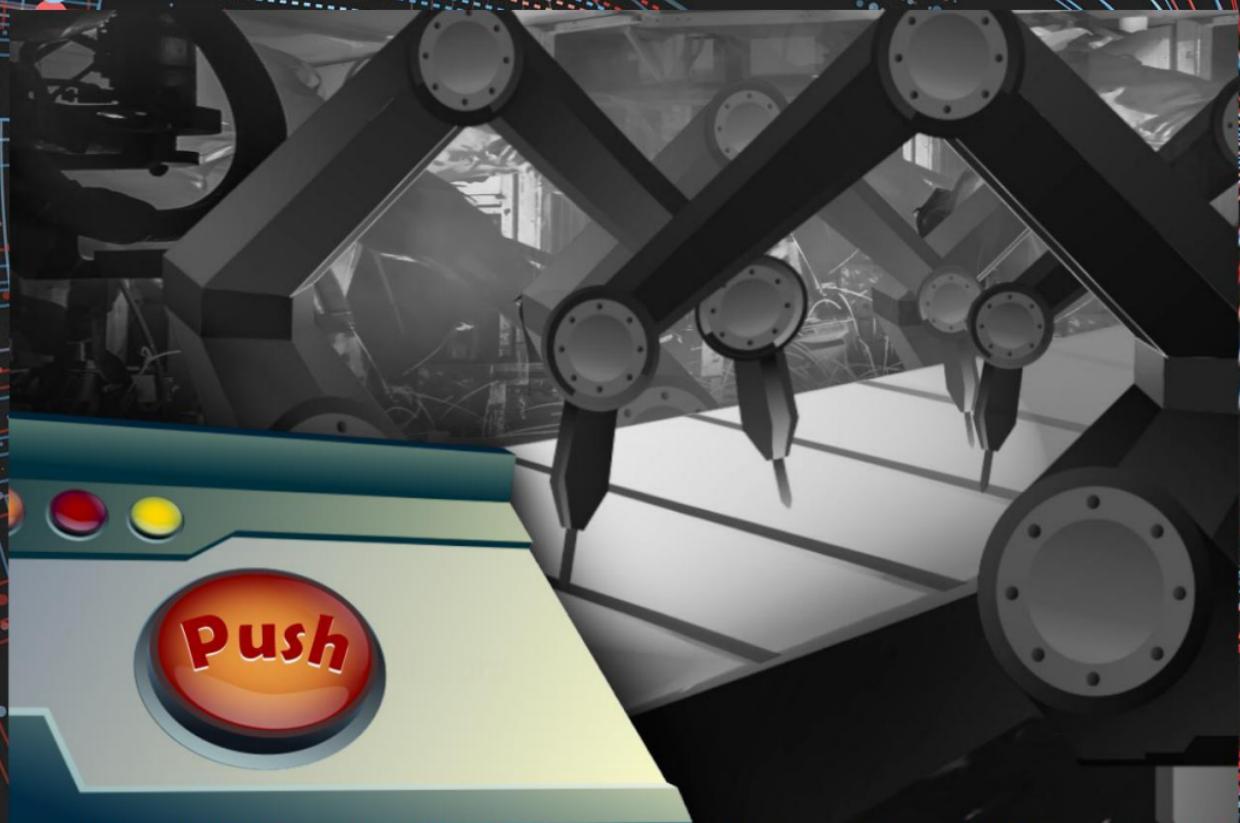

## Reaper

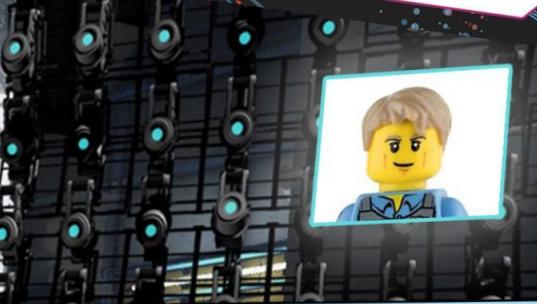

# Base on Mars

# Base on Mars

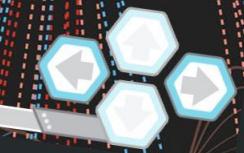

Hello everyone!

Today we woke up to a small earthquake. But it turned out that a large meteorite fell very close to our base! Usually, the study of meteorites provides information about the formation of stars and planets, and therefore meteorite samples can be very valuable. Mars has no atmosphere, so robots will be responsible for collecting samples

ROBORISE-IT!  
ROBOTIC EDUCATION

3

# TASK

## TASK

- collect samples of meteorite debris that fell near the base

## Steps

- learn about how the composition of meteorites tells the story of the universe
- build and program a robot
- collect meteorite samples and deliver them to the base for study

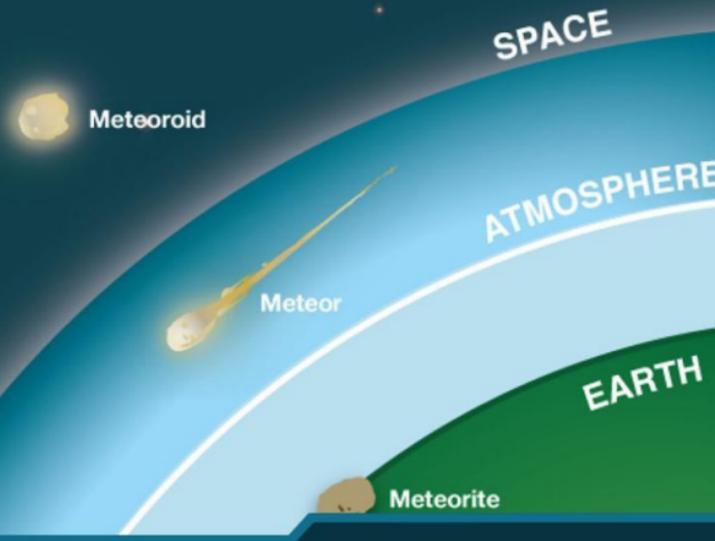

# Meteorites and asteroids

These two concepts are often confused. Asteroids are celestial bodies that orbit the Sun. And meteorites are bodies that fell to the Earth's surface from space. Small asteroids become meteors - bright flashes in the sky

# Meteor streams

Meteors create very beautiful pictures in the night sky. There are periods when the Earth passes through a denser flow and these flashes become very noticeable and frequent. One of the most powerful meteor showers is called the Perseids. It becomes most visible from August 8 to 14

# Task discussion

**When was the last time you watched the night sky?  
What planets, stars or constellations do you know?**

# Meteorites

According to various estimates, 5-6 tons of meteorites fall to Earth every day. And these are only those that can be found and explored. And dust settles in general from 300 to 20,000 tons. Most meteorites weigh from a few grams to several kilograms

# Meteorites

In addition to relatively small meteorites, there are real record holders. The largest is considered to be the Goba meteorite, which fell about 80 thousand years ago on the territory of modern Namibia. It has dimensions of 2.95\*2.84 m, and the height varies from 0.5 to 1.2 m. The weight of this giant is about 60 tons

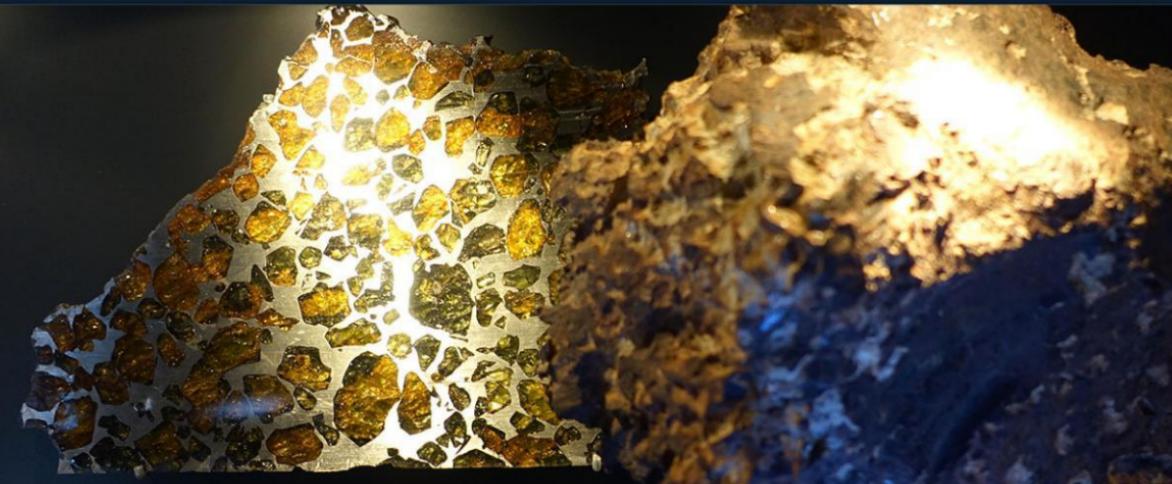

# Meteorites

According to their content, meteorites are divided into three large categories. Most of all stone meteorites (92 out of 100), iron-stone meteorites occur only 2 out of 100 and the rest (6 out of 100 found) are iron meteorites. By the way, Goba also belongs to iron meteorites.

# Meteorites

The study of meteorites can give very interesting results. For example, during the study of the Acfer 086 meteorite, the amino acid glycine was found, which was also part of an extraterrestrial protein. This is not yet extraterrestrial life, but the first brick to it. It is said that such compounds could have formed 4.6 billion years ago.

# Meet the Reaper!

This four-wheeled robot can collect meteorite samples and distinguish them by size!

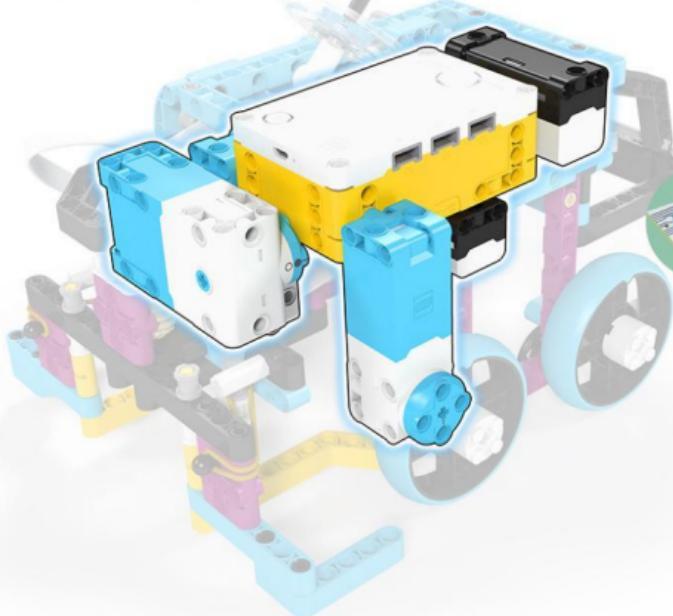

## Reaper

# Design features

The robot is driven by two middle servomotors. A large servo motor is used to drive the manipulator. The color sensor is used for movement along the line, and the distance sensor is used for object recognition

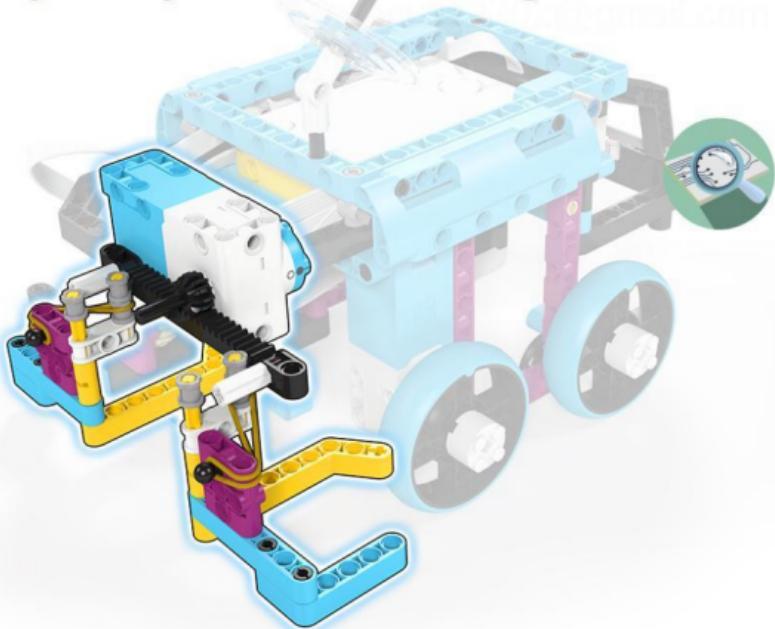

Find:

- Smarthub
- Motors
- Color sensor
- Distance sensor

# Design features

In order for one motor to independently drive two beams, rubber bands are used. They hold the beams in the main position, from which they are displaced by the movement of the gear rack

## Find:

- toothed rack
- manipulator beams
- rubber bands

# Design features

The toothed rack turns the rotation of the motor into translational motion. The parts attached to it deflect the left and right parts of the manipulator

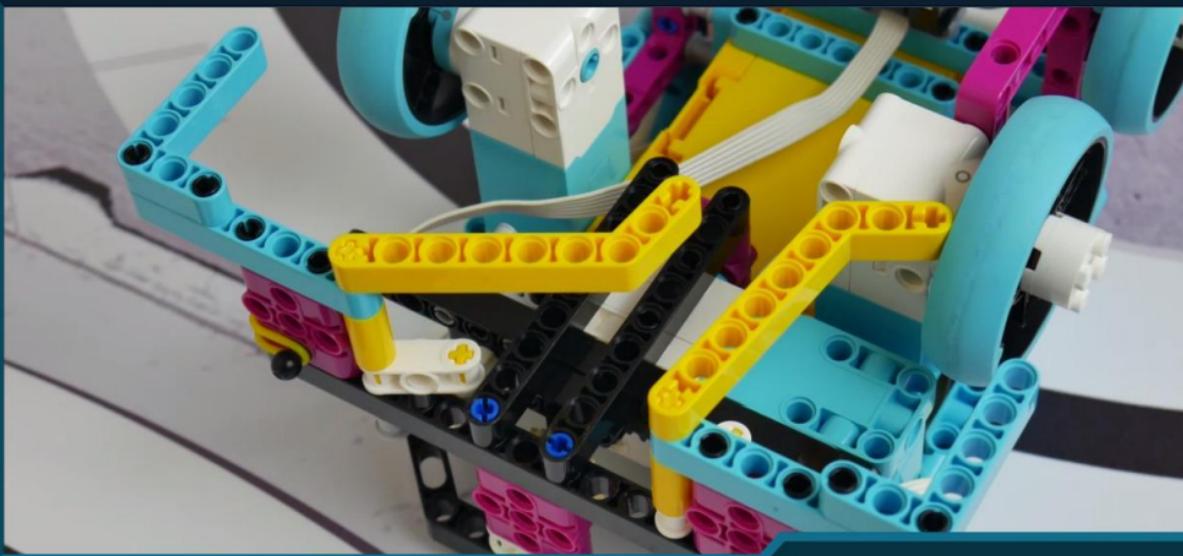

# Design features

When the direction of rotation of the motor changes, the part of the manipulator that captures objects changes. In the central position, the beams do not touch objects and the robot can pass them by moving along the marking line

# Design features

The rear wheels of the robot are driving, and the front wheels play a decorative role. In fact, the robot has two support wheels of small diameter that do not have tires. Thanks to this, the support wheels do not prevent the robot from turning.

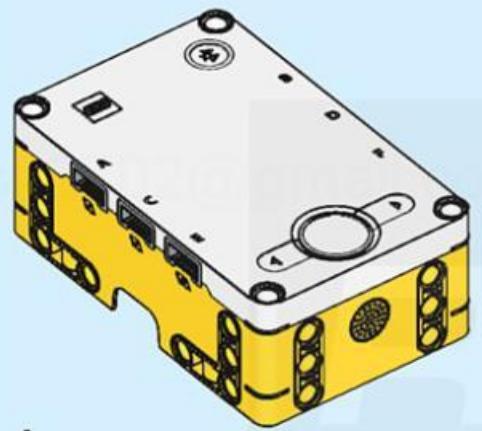

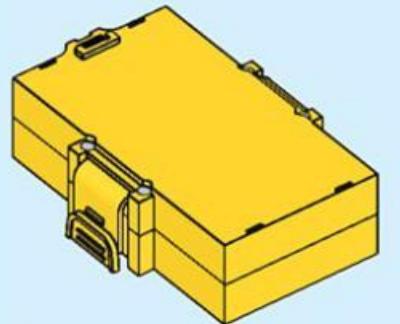

Find:

- Medium motors
- Drive wheels
- Supporting wheels

ROBORISE-IT!  
ROBOTIC EDUCATION

# Check it out!

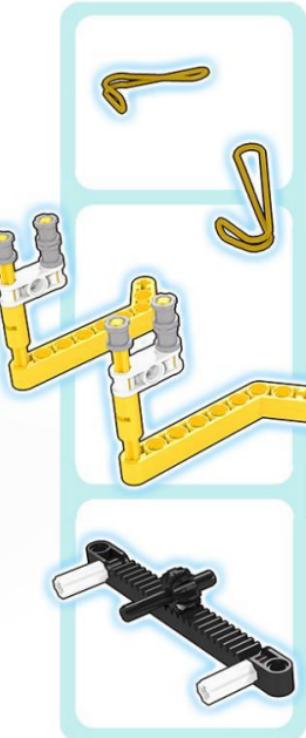

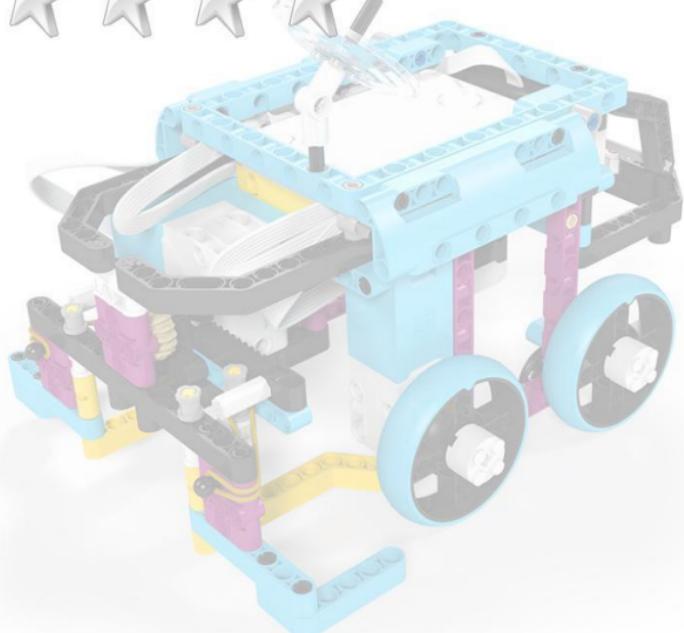

The cables must not rub when the robot is moving!

# Task

Place the parts of the robot in the correct places

# Task

After the meteorite falls, we will use robots to collect samples. At the same time, it is possible to program the collection of samples of any size, or to collect only large or only small fragments of meteorites.

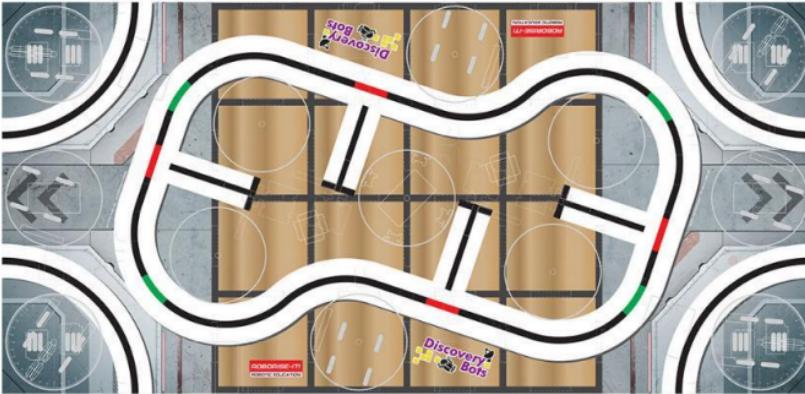

ROBORISE-

# Task field

Take a look at the field assigned to the tasks in this course. It has markings that will help you correctly place objects for tasks, as well as markings for the movement of the robot itself. At the same time, tasks can be performed by two, and sometimes four teams!

Please note that if the field is printed in such a way that the robot sensor does not correctly detect the colors, you can cover the corresponding areas with self-adhesive films "Oracal".

# Task 1

Program the movement of the robot along the marking line. This is how you indicate to it the route for collecting samples

**ROBORISE-IT**

[ROBORISEIT.COM](http://ROBORISEIT.COM)

# Task 1. Program

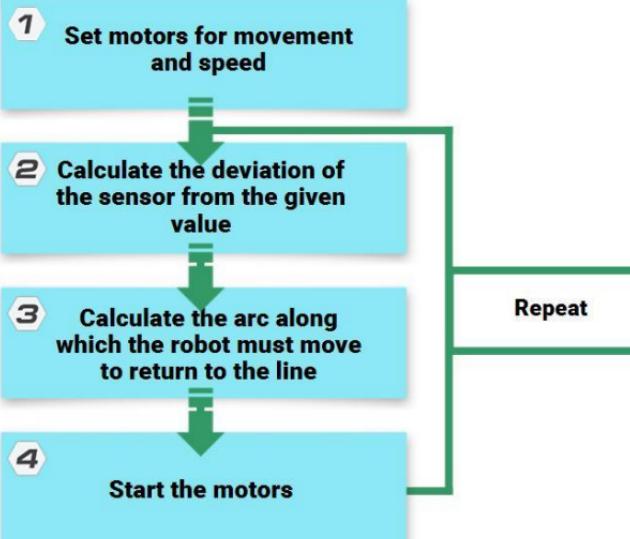

Algorithm

Program

The robot movement algorithm along the marking line using a proportional regulator is as follows:

# Task 1. Program

Algorithm      Program

The program may look like this:

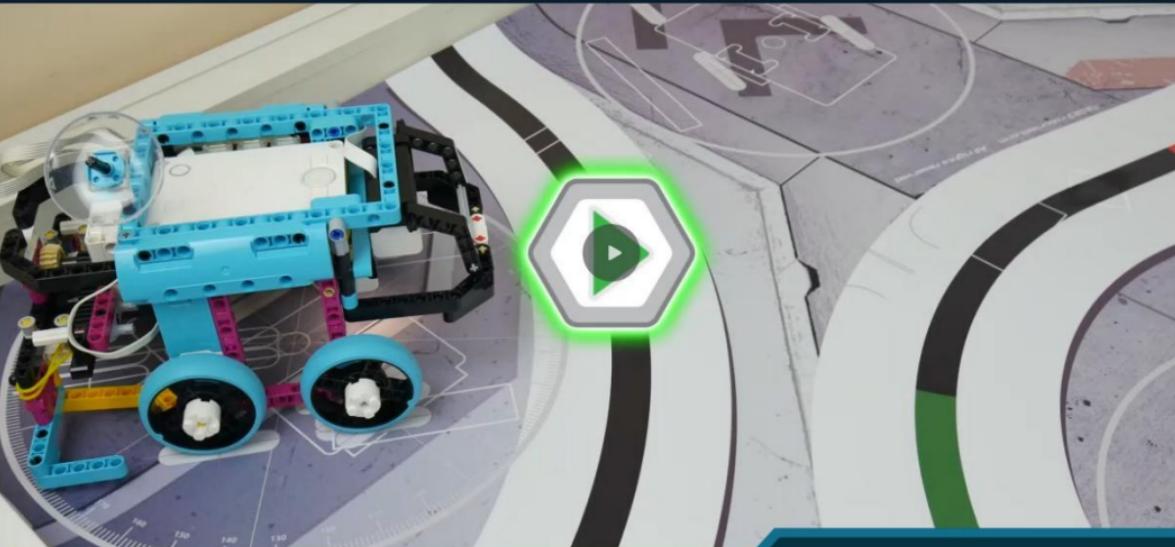

```
when program starts
  set movement motors to [B + A v]
  set movement speed to [15 %]
forever
  start moving
  if [reflected light v] is between [22] and [7]
    stop movement
```

## Task 2

Add departure from the base to your program. The robot must find the marking line and stop in a position convenient to continue moving along it.

# Task 2. Program

Algorithm

Program

The algorithm for leaving the marking line can look like this:

- 1 Set motors for movement, speed and travel distance in 1 turn
- 2 Drive 30 cm and start moving forward
- 3 Wait a reduction in reflected light value of less than 22%
- 4 Stop the motors

# Task 2. Program

Algorithm

Program

The program may look like this. Please note that journey times may differ when starting from another base!

```
when program starts
  set movement motors to [B + A v]
  set movement speed to [15 %]
  set 1 motor rotation to [17.5 cm v] [moved v]
  move [↑ v] for [30 cm v]
  start moving [straight: 0]
  wait until [reflection v] [at [22 %] ?]
  stop moving
```

## Task 3

Combine the two previous programs and test them. The robot must leave the base, find the marking line and continue moving along it

# Task 3. Program

Algorithm

Program

To perform the assigned task, the program must work according to the following algorithm:

1 Leave the base to the marking line

2 Move along the marking line

# Task 3. Program

Algorithm      Program

The combined program looks like this:

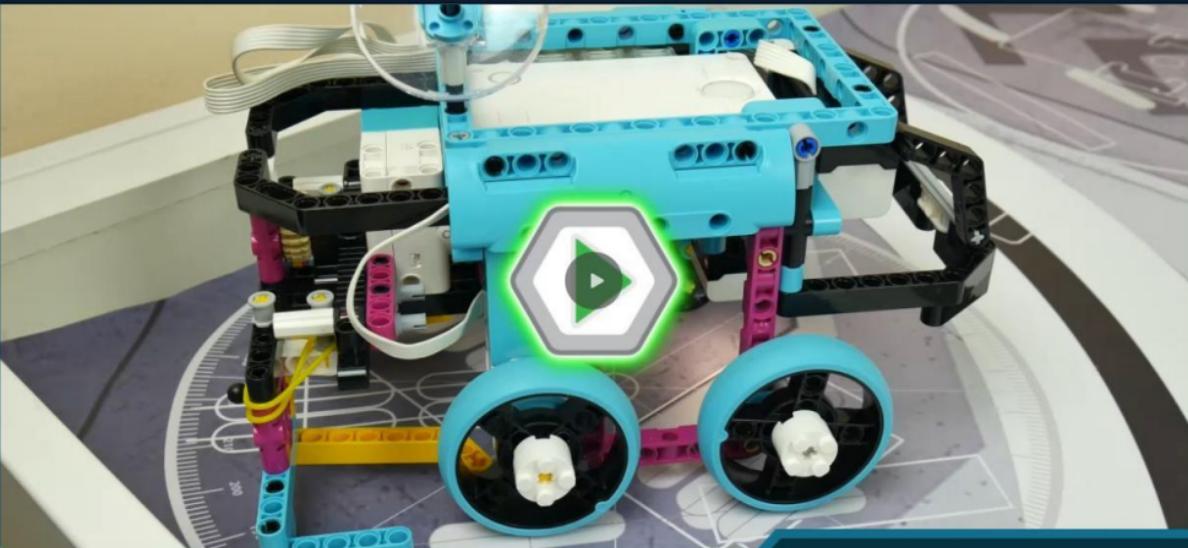

```
when [Task 3] starts
  set [movement motors v] to [B + A]
  set [movement speed v] to [15 %]
  set [1 motor rotation v] to [17.5 cm]
  move [30 cm] for [17.5 cm v]
  start moving [straight v: 0]
  wait until [reflected light v: 22 %?]
forever
  start moving [straight v: 0]
  wait until [reflected light v: 22 %? * 7]
```

## Task 4

Your robot is ready to work with meteorite samples. To be able to capture them, program the manipulator calibration. In the central position, the manipulator beams should pass through the samples and not displace them during movement

# Task 4. Program

Algorithm

Program

The calibration algorithm can be as follows:

- 1 Move the manipulator to the extreme left position
- 2 Reset the motor speed sensor data
- 3 Move the manipulator to the extreme right position
- 4 Calculate the central position and transfer the manipulator to it

# Task 4. Program

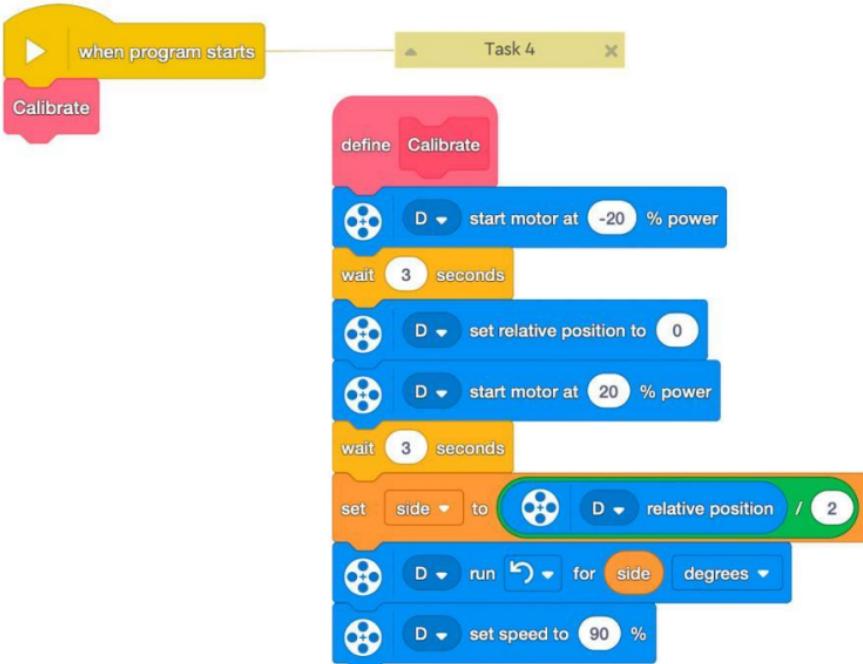

Algorithm

Program

Create a 'My block' for convenient use of the calibration program:

```
when program starts
  Calibrate
  [Calibrate v]
  define [Calibrate v]
    start motor at [20% power]
    wait [3 seconds]
    set [relative position v] to [0]
    start motor at [20% power]
    wait [3 seconds]
    set [side v] to [relative position / 2]
    run [for [side] degrees]
    set speed to [90% power]
```

# Task 5. Program

Algorithm

Program

The algorithm can be as follows:

- 1 Adjust the motors for movement
- 2 Calibrate the position of the manipulator
- 3 Leave the base to the marking line
- 4 Move along the line

# Task 5. Program

Algorithm

Program

The modified program looks like this:

```
when program starts
  set movement motors to [B + A v]
  set movement speed to [15 %]
  set 1 motor rotation to [17.5 cm v] [moved]
  Calibrate
  move [30 cm v] for [1 v]
  start moving straight: [0]
  wait until [reflection of (C) v is [22 %] ?]
forever
  start moving [when green flag is shown v]
  if [reflected light of (C) v is [22 %] and [7 %] v]
  then
    stop
  end
```

## Task 6

Add tracking of the presence of meteorite debris on the robot's trajectory and the corresponding reaction in the form of changes in the proportional controller.

# Task 6. Program 1

Algorithm

Program

Add proportional controller control via variable value and sending a message to start tracking for debris:

The script starts with a 'when program starts' hat block. It initializes movement with 'set movement motors to B+A', 'set movement speed to 15 %', and 'set 1 motor rotation to 17.5 cm moved'. It then performs a 'Calibrate' step. Following this, it moves forward with 'move ↑ for 30 cm', starts moving straight with 'start moving straight: 0', and waits until a 'C reflection < 22 % ?' condition is met. At this point, it sends a 'broadcast start' message. The script then enters a 'forever' loop, which contains a 'start moving' block with a 'C reflected light - 22' condition and a 'k' variable. The script is titled 'Task 6'.

# Task 6. Program 2

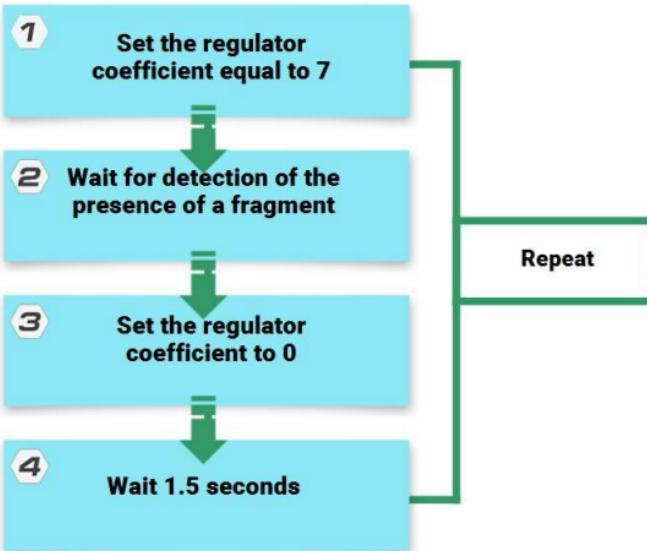

Algorithm

Program

The algorithm for responding to the presence of debris on the trajectory can be as follows:

# Task 6. Program 2

Algorithm

Program

According to the following program, the robot will drive along the line with a coefficient of 7, and when detecting a fragment, it will shake hands for 1.5 seconds straight (the coefficient is equal to 0).

```
when I receive [start v]
forever
  [set [k] v [7]
  wait until [F v is closer than v [6.5] cm v ?]
  set [k] v [0]
  wait [1.5] seconds]
```

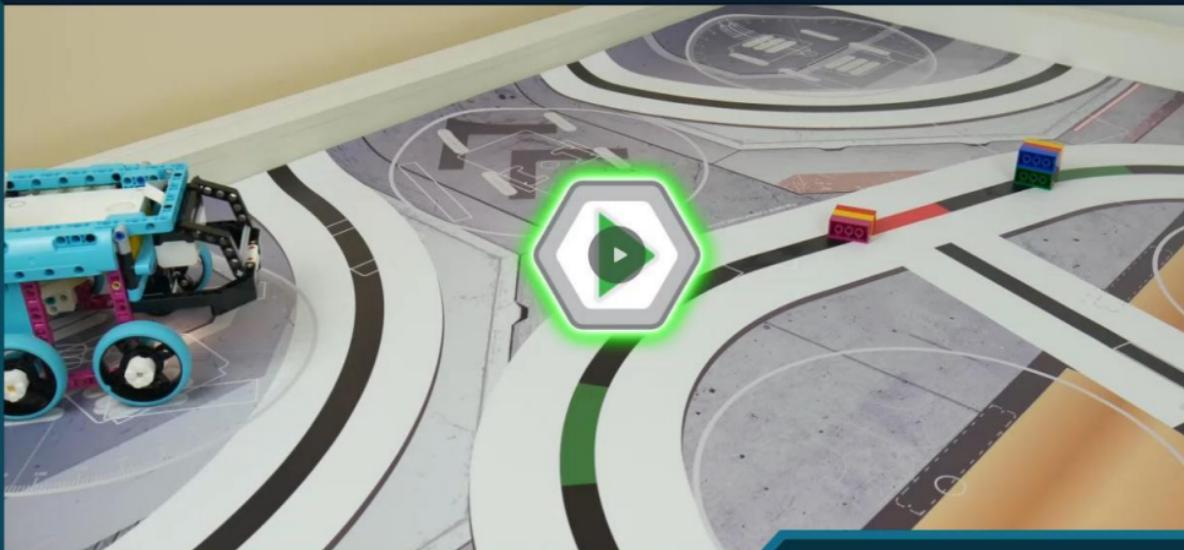

Scratch.com

# Task 7

Program the collection of meteorite fragments. Large and small debris should go to different compartments.

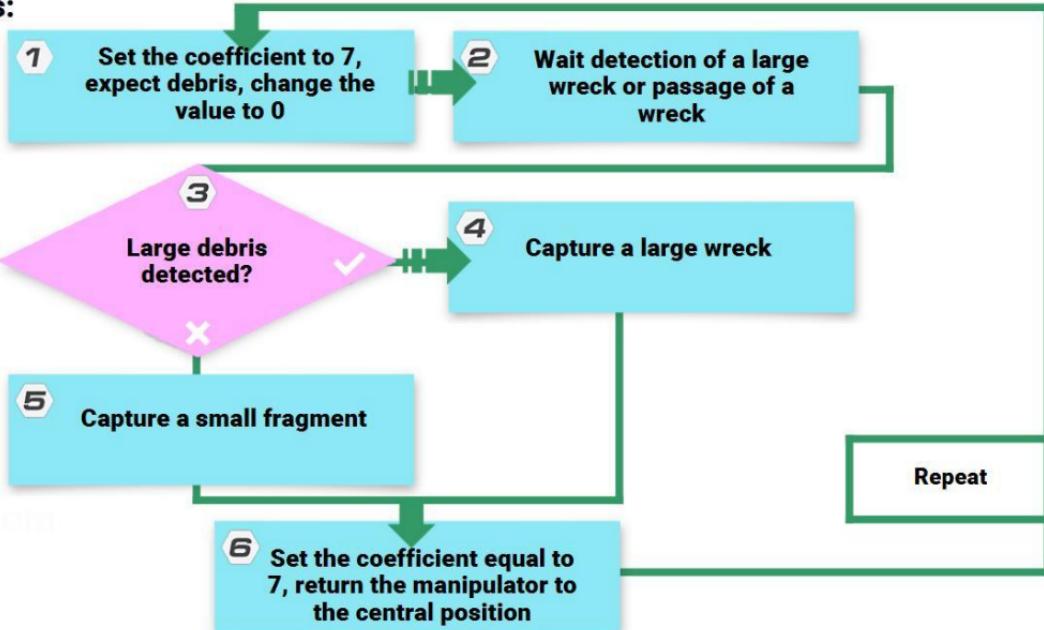

# Task 7. Program

Algorithm      Program

The algorithm for responding to the presence of debris on the trajectory can be as follows:

# Task 7. Program

Algorithm

Program

The updated program may look like this:

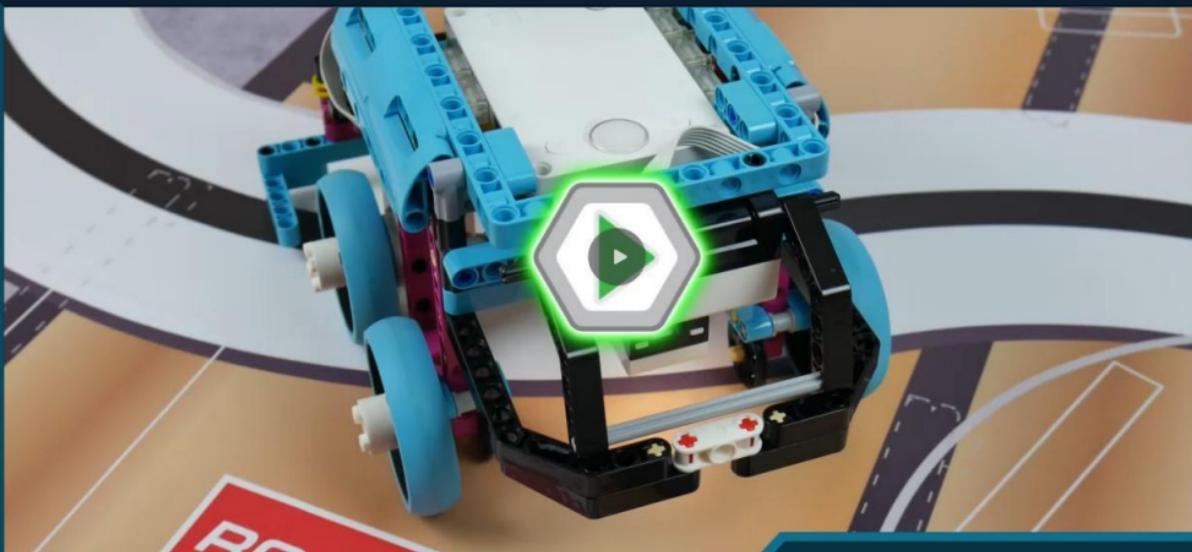

```
when green flag is clicked
repeat (10)
  set [k v] to [7]
  wait until [F v] is closer than [6.5 cm v]
  set [x v] to [0]
  if [F v] is closer than [5 cm v] then
    [D v] run [180 degrees v] for [0.2 seconds v]
    set [x v] to [7]
    wait [0.7 seconds v]
  else
    [D v] run [180 degrees v] for [0.2 seconds v]
    set [x v] to [7]
    wait [0.7 seconds v]
end
```

## Task 8

To determine the position of the robot on the line, there are red and green color zones. Check if the color sensor can detect the color of these zones from the height at which it is placed.

# Task 8. Program

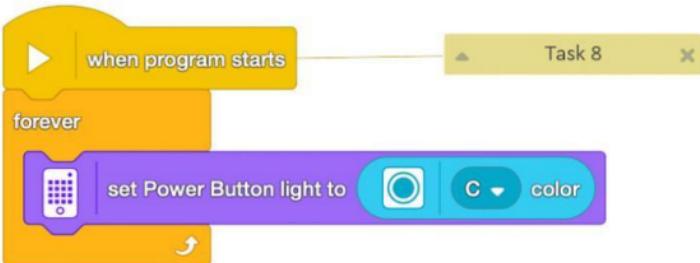

Algorithm

Program

The test program may look like this:

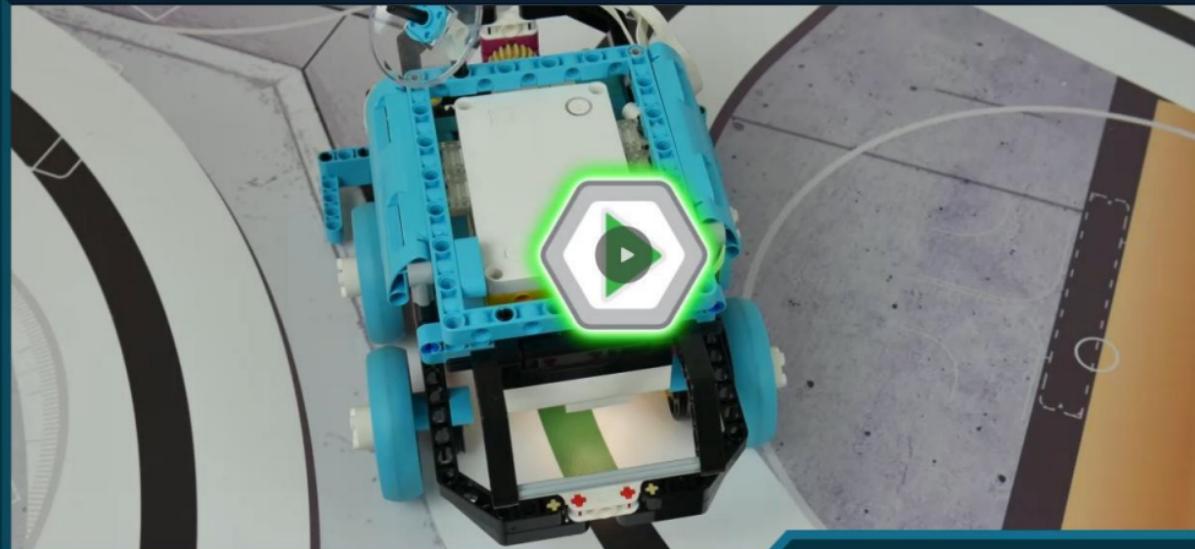

## Task 9

To determine the color from such a Vistana, you can use the reading of the color components (green, blue and red). If the reflected signal is dominated by a red component, then most likely the sensor is aimed at a red surface, etc.

# Task 9. Program

Algorithm

Program

The test program may look like this:

```
when program starts
forever
  set Power Button light to [red v]
  write [C v] [raw v] [red v]
  wait (1) [seconds v]
  set Power Button light to [green v]
  write [C v] [raw v] [green v]
  wait (1) [seconds v]
  set Power Button light to [blue v]
  write [C v] [raw v] [blue v]
  wait (1) [seconds v]
```

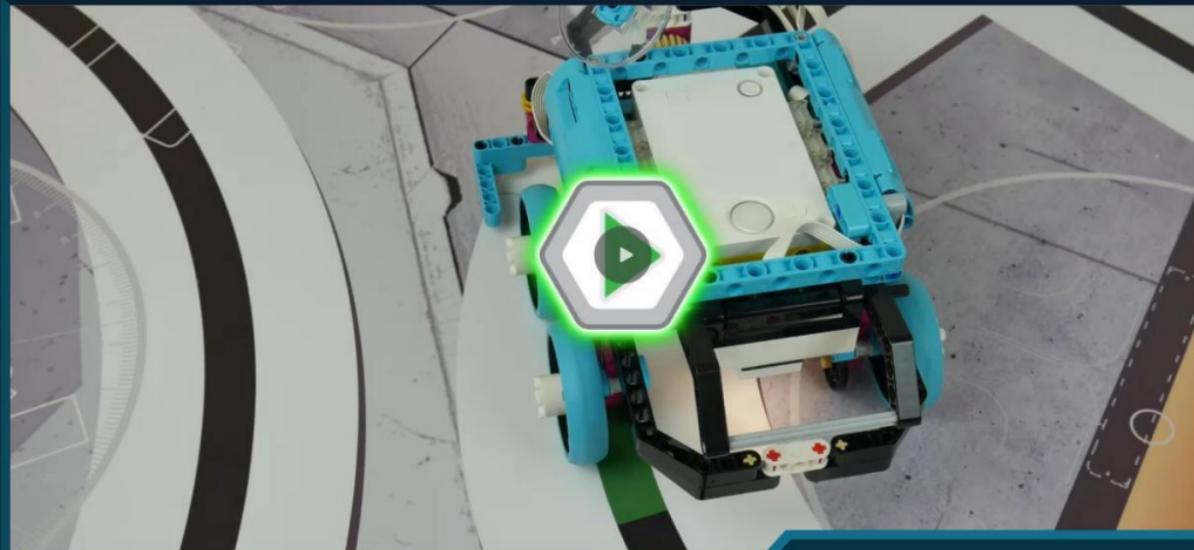

# Task 10

To complete the movement along the marking line, the robot must be able to count the number of green zones it passes. Test the following program to see if the robot 'sees' the green area and adjust it as needed

# Task 10. Program

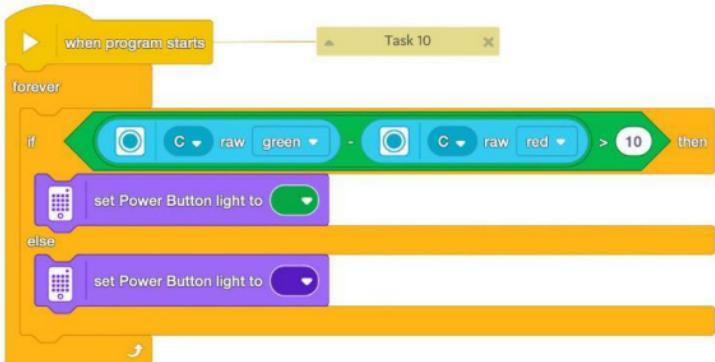

Algorithm

Program

The test program may look like this:

# Task 11

Write a program in which the robot leaves the base, picks up one small and one large piece of debris, and returns to the base after detecting the fourth green zone on the trajectory

# Task 11. Program 1

Algorithm

Program

The updated program may look like this:

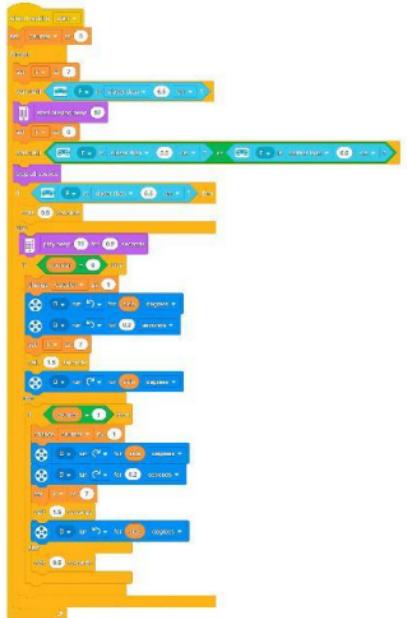

```
when program starts
  set [exit v] to [0]
  set [movement motors v] to [B + A]
  set [movement speed v] to [15 %]
  set [1 motor rotation v] to [17.5 cm] and [moved]
  Calibrate
  move [↑ v] for [30 cm] [cm]
  start moving [straight: 0]
  wait until [C reflection v] is [22 %] [?]
  stop moving
  broadcast [start v]
  repeat until [exit v] = [1]
    start moving [C v] [reflected light v] is [22 %] [?]
    play [beep v] [84] for [0.2] [seconds]
    move [left: -20 v] for [3] [rotations]
  end
  play sound [ ] v
```

## Task 11. Program 2

Algorithm  Program 

**The updated program may look like this:**

# Task 11. Program 3

Algorithm

Program

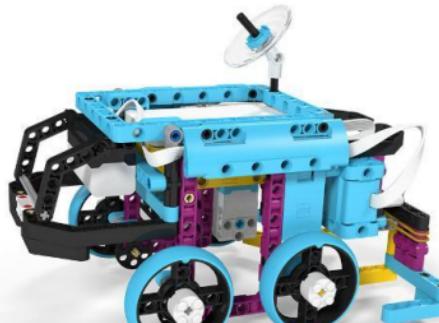

The updated program may look like this:

```
when I receive [start]
repeat (3)
  wait until [light green > 10 and light red > 0]
  play beep [60] for [0.2] seconds
  wait [5] seconds
end
set [exit] to [1]
```

# Discuss!

- ▶ What event happened near your base on Mars?
- ▶ How do meteorites differ from asteroids and meteors?
- ▶ What types of meteorites do you know?
- ▶ What celestial bodies have you observed yourself?
- ▶ How did your robot distinguish the size of meteorites?
- ▶ What sensor is used to program the movement of the robot along the line?
